

Repositioning Cisco Webex for the Next Phase of Hybrid Work

Three Strategic Problems & AI-Powered Solutions

Spring 2026 Cisco x WiB x SWE Case Competition

Binghamton University

March 2026

Executive Summary

Cisco Webex faces three critical strategic problems that prevent it from competing effectively against Microsoft Teams and Zoom in the next phase of hybrid work. This document identifies each problem with specificity, proposes a targeted AI-powered solution backed by Cisco's existing capabilities, provides detailed technical flowcharts, and assesses the technical feasibility, constraints, scalability, implementation risks, and system-level trade-offs of each solution.

The three problems and their corresponding solutions are:

- Problem 1: Webex AI cannot execute or operationalize meetings. The AI Assistant is passive: it summarizes and transcribes but does not prepare users beforehand, execute tasks during meetings, or follow up afterward. Solution: Deploy the Webex AI Meeting Prep & Workflow Orchestrator, a Prepare-Perceive-Reason-Act-Follow-Up system that covers the full meeting lifecycle with agentic AI and human-in-the-loop verification.
- Problem 2: Webex meetings exclude non-native speakers and non-technical participants. Language barriers, technical jargon, poor audio quality, and inability to speak in noisy or sensitive environments create participation gaps that reduce meeting value. Solution: Build VIBE (Voice & Language Intelligence Layer), a real-time in-meeting AI layer that boosts voice, translates between languages, simplifies jargon, and enables type-to-speak.
- Problem 3: Webex has a weaker, less strategic developer ecosystem. Teams has 2,000+ integrations, Zoom has 2,500+, and neither has launched a dedicated AI agent development platform. Solution: Launch the Secure AI Agent Marketplace with a developer SDK, Cisco security certification pipeline, and enterprise deployment infrastructure supporting hundreds of third-party integrations.

Each solution leverages Cisco's existing competitive advantages: the \$7.98 billion R&D budget, the \$28 billion Splunk acquisition for enterprise data observability, FedRAMP/HIPAA/SOC 2 Type II security certifications, and the Webex AI Codec's proven ML engineering capabilities.

Problem 1: Webex AI Cannot Execute or Operationalize Meetings

Problem Definition

The Webex AI Assistant is still primarily passive: it generates meeting summaries, real-time transcription, and language translation. These features are now baseline across collaboration platforms and do not meaningfully change how work gets done. Webex AI tells users what happened in a meeting, but it neither prepares them effectively beforehand nor acts on the decisions made during the meeting.

This creates a measurable productivity gap across the full meeting lifecycle:

- Before meetings, users manually prepare slides, agendas, and talking points, often under time pressure and without structured guidance on what stakeholders actually care about.
- During meetings, when a manager says "Create a Jira ticket for the login bug Sarah found" or "Update the Salesforce opportunity for ACME," nothing happens automatically.
- After meetings, presenters must recall details, open multiple tools (Jira, Salesforce, ServiceNow), create or update items by hand, and send follow-up answers to questions they could not address live.

Each of these steps takes time and introduces errors from memory decay and context switching. Manually creating a single Jira ticket from meeting notes can take 8-12 minutes; preparing an entire deck for a stakeholder meeting can take hours. Across dozens of meetings per week, this compounds into lost time and missed follow-ups.

Competitive Gap Analysis

Microsoft Teams with Copilot can draft Word documents from meeting context, create PowerPoint presentations, generate Excel formulas, and build Power Automate workflows that connect across the Microsoft Graph. Copilot uses organizational context from emails, files, calendars, and chats to proactively suggest content and automate steps before and after meetings.

Zoom AI Companion 2.0 similarly includes early agentic features: it drafts documents in Zoom Docs, automatically generates action items with assignees, updates CRM records through Zoom Revenue Accelerator, and drives workflow automation inside the Zoom ecosystem at no additional cost to paid users.

In contrast, Webex AI is largely descriptive. It can summarize and transcribe but does not proactively help users prepare for meetings, execute tasks in third-party systems, or close the loop on unanswered questions. The gap is not incremental; it is categorical. Competitors have AI that prepares and does work. Webex has AI that describes work, leaving humans to manually perform everything around the meeting.

Business Impact of the Problem

- User engagement stagnation: Users treat Webex as a "join and talk" tool rather than a productivity engine. Because Webex does not help them prepare, execute, or follow up, they spend less time in the product and more time in surrounding tools, reducing stickiness and increasing churn risk.
- Enterprise deal losses: In RFPs, IT decision-makers increasingly compare end-to-end AI workflows, not just summaries. When buyers see Copilot and Zoom AI Companion drafting content and taking actions while Webex AI remains passive, Webex loses competitive evaluations.
- Revenue ceiling: Without differentiated, action-oriented AI, Webex's collaboration revenue faces a growth ceiling as the market shifts toward platforms that can reduce prep

time, automate task execution, and tie into enterprise workflows.

Solution 1: Webex AI Meeting Prep & Workflow Orchestrator

Transform the Webex AI Assistant from a passive summarization tool into an agentic AI system that: (1) prepares users before the meeting with agendas, insights, auto-generated slides, and predicted questions; (2) perceives task intents and decisions during the meeting from live conversation; (3) reasons over enterprise context using secure integrations and organizational rules; (4) acts by drafting complete task artifacts and executing approved actions across third-party platforms; and (5) follows up on unanswered questions after the meeting with structured, trackable responses. The system operates on a Prepare-Perceive-Reason-Act-Follow-Up architecture with mandatory human-in-the-loop verification for all external actions.

PREPARE Phase: AI Meeting Prep & Slide Assistant

Before the meeting begins, Webex AI proactively assists the presenter:

- Context Ingestion: When a meeting is scheduled, Webex ingests the title, invite description, participant list, and attached documents, and where authorized, relevant records from CRM, project tools, and past meeting transcripts.
- Insight & Agenda Suggestions: The AI generates key insights and metrics likely to matter to the invited stakeholders, along with a suggested agenda (sections such as "Status," "Risks," "Decisions Needed," "Q&A").
- Prep Checklist: The agent creates a structured checklist (e.g., "Upload latest metrics deck," "Confirm owner for customer escalation," "Prepare answer on Q3 budget impact").
- Auto-Slide Generation: If the presenter opts in, Webex AI generates a first-draft slide deck using meeting context and enterprise data (CRM pipeline, Jira issues, financial metrics), organized into the proposed agenda.
- Predicted Q&A: The AI predicts likely questions based on role, history, and topic, and suggests draft answers the presenter can review, refine, or reject.

PERCEIVE Phase: Webex AI Codec ML Pipeline

During the live meeting, the existing Webex AI Codec serves as the perception layer:

- Deep Neural Network (DNN) Noise Removal: Real-time models remove background noise (keyboards, dogs, construction, etc.), isolating clean speech.
- Neural Speech Synthesis Codec: Cleaned audio is compressed using a neural codec to maintain high quality even on low bandwidth.
- Real-Time Media Models (RMM): AI upscales low-resolution video, separates individual speakers, and detects gestures/reactions.
- NLP Engine: Speech is converted to text with real-time transcription and translation. The NLP layer identifies task-related statements, decisions, commitments, and live occurrences of predicted questions from the PREPARE phase.

REASON Phase: Context Retrieval and Task Planning

- Context Retrieval via Agent-to-Agent (A2A) Protocols: Webex AI communicates with external system agents (Jira, Salesforce, GitHub, ServiceNow) through standardized protocols to retrieve relevant context.
- Cisco Secure Data Fabric & Observability: All retrieval passes through Cisco's zero-trust identity and access layer. Every call is monitored via Splunk observability tools.
- LLM-Based Task and Answer Planning: A large language model synthesizes live meeting context, retrieved system data, and organizational policies to generate complete

task drafts or follow-up plans.

ACT Phase: In-Meeting Human Verification and Execution

- In-Meeting Draft Cards: The user sees a non-disruptive overlay showing the fully drafted task artifact or follow-up response.
- Approve / Edit / Reject Controls: The user can approve, edit, or reject each draft.
- Secure Execution & Logging: On approval, the agent executes through authenticated API calls. Every step is logged for auditing and compliance.
- Meeting Chat Confirmation: Webex posts a concise confirmation back into the meeting chat.

FOLLOW-UP Phase: Structured Q&A and Post-Meeting Delivery

- Unanswered Question Detection: The system identifies questions that were asked but not answered or explicitly deferred.
- Q&A Follow-Up Drafts: For each unanswered question, the AI drafts a suggested response and presents it to the owner for approval/edit.
- Multi-Channel Delivery: Approved answers are sent to participants via Webex spaces, email, or integrated systems, optionally simplified for non-technical speakers.
- Visibility & Observability: All follow-up actions are logged and visible through Splunk dashboards.

Why This Enhanced Solution Wins

This solution brings Webex from a passive summarization tool to an agentic AI system that covers the full meeting lifecycle. Where Microsoft Copilot and Zoom AI Companion focus primarily on content generation and partial task execution inside their own ecosystems, Webex differentiates by owning the full Prepare-Perceive-Reason-Act-Follow-Up loop with strong guardrails and regulated-industry readiness.

Expected Impact

- Reduces manual post-meeting data entry by 15 minutes per meeting
- 25% meeting-to-action conversion rate (vs. current ~5% industry average)
- 40% workflow automation rate within 12 months of deployment
- 85% task completion accuracy with human-in-the-loop verification
- 90%+ Q&A resolution rate through structured post-meeting follow-up

Solution 1 Flowchart: Prepare-Perceive-Reason-Act-Follow-Up

The following flowchart details the complete five-phase architecture including pre-meeting AI prep, the AI Codec ML pipeline, data fabric integration, human-in-the-loop verification, cross-platform task execution, and post-meeting Q&A follow-up.

Solution 1: Webex AI Meeting Prep & Workflow Orchestrator

Prepare → Perceive → Reason → Act → Follow-Up | Full Meeting Lifecycle AI

Problem 2: Webex Meetings Exclude Non-Native and Non-Technical Participants

Problem Definition

Hybrid and global workforces are now the norm. Enterprises routinely run meetings with participants spread across countries, languages, and technical backgrounds. Yet collaboration platforms treat meetings as though everyone speaks fluent English, understands technical jargon, has a quiet environment, and can always speak aloud. This creates systemic exclusion:

- Language barriers: Non-native English speakers struggle to follow fast-paced discussions, miss nuances, and hesitate to ask questions.
- Technical jargon: In cross-functional meetings, technical terminology alienates non-technical participants. When an engineer says "the API rate limiter is throttling at the gateway," a sales leader hears noise, not information.
- Poor audio quality: Users in noisy environments produce audio that degrades the experience for all participants and makes AI transcription inaccurate.
- Inability to speak: Some participants cannot speak aloud due to noise, broken microphones, speech difficulties, or social anxiety in large meetings. These users are effectively silenced.

Competitive C

Microsoft Teams offers live captions and basic translation, but these are read-only text overlays that do not address voice quality, jargon simplification, or the inability to speak. Zoom provides similar caption-based translation. Neither platform offers a comprehensive voice intelligence layer that cleans, boosts, translates, simplifies, and speaks on behalf of users in real-time.

Business Impact of the Problem

- Reduced meeting ROI: When 30-40% of participants cannot fully engage due to language or audio barriers, meetings produce lower-quality decisions.
- Global team friction: Language barriers are the number one obstacle to effective cross-border collaboration.
- Accessibility gaps: Users with speech difficulties or social anxiety are systematically excluded from verbal participation.
- Competitive vulnerability: As enterprises prioritize DEI in technology procurement, platforms that do not solve participation barriers will lose.

Solution 2: VIBE - Voice & Language Intelligence Layer

VIBE is a real-time, in-meeting voice and language AI layer that boosts and cleans voice quality, translates between native and English in both speech and text, simplifies technical jargon for non-technical users, and enables type-to-speak so VIBE speaks on the user's behalf. All inside Webex. No deepfake risk. Every action is auditable and transparent.

A: User Entry & Onboarding

- Toggle Activation: A VIBE toggle appears in the meeting controls bar. Zero configuration required.
- Mode Selection: Voice Boost, Live Translation, Type-to-Speak, and/or Simple Mode (jargon simplification). One or more modes active simultaneously.
- Language & Profile: Native language (Hindi, Spanish, Mandarin, French, Arabic, Portuguese, Japanese, Korean, +90 more), tech level (Technical/Non-Technical), voice preset (Clear, Loud, Warm, Broadcast-style).

B: Live Audio Path - When User Speaks

- Microphone Audio Captured: Raw PCM stream with per-speaker separation via Webex

AI Codec.

- Audio Intelligence Front-End: DNN noise removal for 150+ noise types, echo cancellation, auto gain control, smart room detection with reverb and acoustic fingerprint adjustment.
- Voice Boost & EQ Engine: Applies selected preset, adapts to environment, normalizes waveform for consistent output.
- Speech-to-Text (ASR): Real-time transcription with multi-accent support, per-speaker diarization, filler word removal.
- NLP Layer - Conditional Processing: Simple Mode rewrites jargon to plain language with analogies (e.g., "API" becomes "a waiter between kitchen and table"). Translation converts native language to English or target. Always-active intent tagging and clarity scoring.
- Text-to-Speech: VIBE Voice with consistent persona, emotional tone matching.
- Delivered to All Participants: Cleaned, boosted, translated VIBE voice with per-user captions in their own language.

C: Type-to-Speak Path - When User Cannot Speak

- Triggers: Muted, too noisy, broken mic, speech difficulty, large-meeting shyness. Auto-suggest when VIBE detects prolonged silence + high ambient noise.
- User types in VIBE Panel in any language. Can paste code, data, tables. Drafts visible only to user before send.
- NLP Processing: Detect language, translate to meeting language, apply "Polish mode" to convert draft into fluent spoken-style language.
- VIBE Agent Speaks: Neural TTS speaks typed message aloud. Label: "Spoken by VIBE for [UserName]." Three voice personas per session.
- Caption & Chat Sync: "from [UserName] via VIBE" tag in transcript. Chat logs typed input + spoken output side-by-side.

D: Q&A Close-Loop for Non-Native / Non-Technical Users

- User Asks in Own Language via voice or type-to-speak.
- ASR + Translation to English for the presenter.
- Presenter answers in English; VIBE captures answer in real-time.
- Translation + Simplification back to user: English answer translated to native language. Simple Mode adds analogy and concrete example.

E: End & Logging

- VIBE Transcript: Original language layer, English translation layer, simplified text layer, timestamps + speaker IDs, Type-to-Speak logs marked.
- VIBE Summary Pack: Key Q&A in native language with simple explanations, downloadable per-user, shareable via Webex/email.
- Session Analytics (Splunk-Powered): Voice clarity score trend, translation accuracy log, Q&A resolution rate, VIBE usage breakdown. All session data flows into Splunk for enterprise-wide observability, anomaly detection, and compliance reporting.

Privacy Guarantee: Transparency & Trust Layer

- Every VIBE-synthesized voice is labeled: "Spoken by VIBE for [User]." No hidden AI speech.
- Full audit trail: every VIBE action (boost, translate, TTS, simplify) logged with user consent timestamps and streamed to Splunk for centralized governance.
- Splunk VIBE Dashboard: Enterprise IT teams monitor voice quality metrics, translation accuracy, TTS usage patterns, and anomalous VIBE behavior across all meetings in

real-time.

- Zero data retention option: transcript deleted on meeting end if user opts out.
- VIBE never impersonates: voice persona is distinct from user's actual voice.

Why This Solution Wins

No collaboration platform today offers a unified, real-time voice and language intelligence layer. Teams and Zoom provide basic captions and translation as passive overlays. VIBE goes far beyond by actively improving voice quality, translating with TTS delivery, simplifying jargon with analogies, and enabling silent users to speak through AI. Combined with Cisco's AI Codec technology and Splunk-powered observability for enterprise-wide monitoring of voice quality, translation accuracy, and compliance, VIBE creates a participation experience that makes every meeting truly inclusive and governable at scale.

Expected Impact

- Noise reduction effectiveness: 95%+ across 150+ noise types
- ASR accuracy: 98% real-time transcription accuracy
- Translation latency: <1 second end-to-end
- TTS naturalness: 4.5/5 user rating target
- Type-to-speak delivery: <2 seconds from send to spoken output
- 40% increase in non-native speaker participation rates

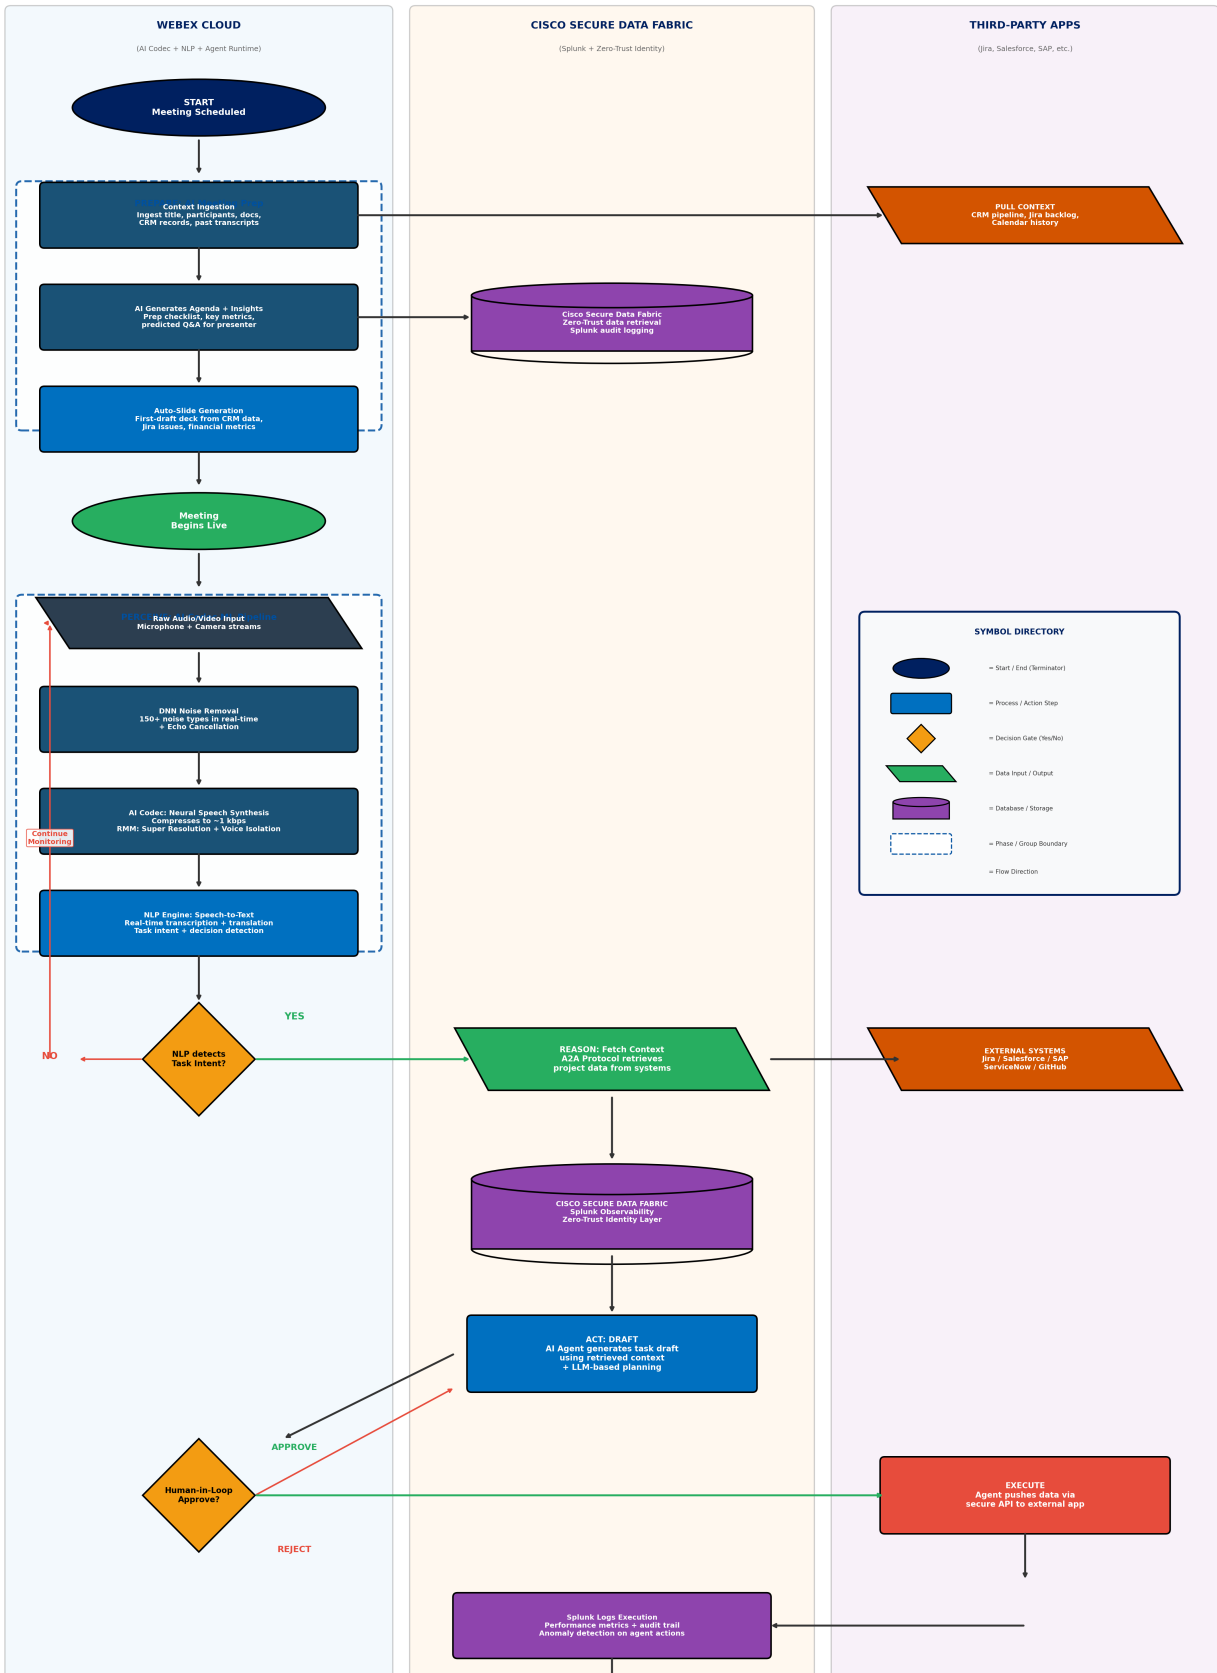

Sources: Cisco Webex AI Codec documentation; Microsoft Work Trend Index 2024; Gartner DEI in Technology Procurement Report 2024.

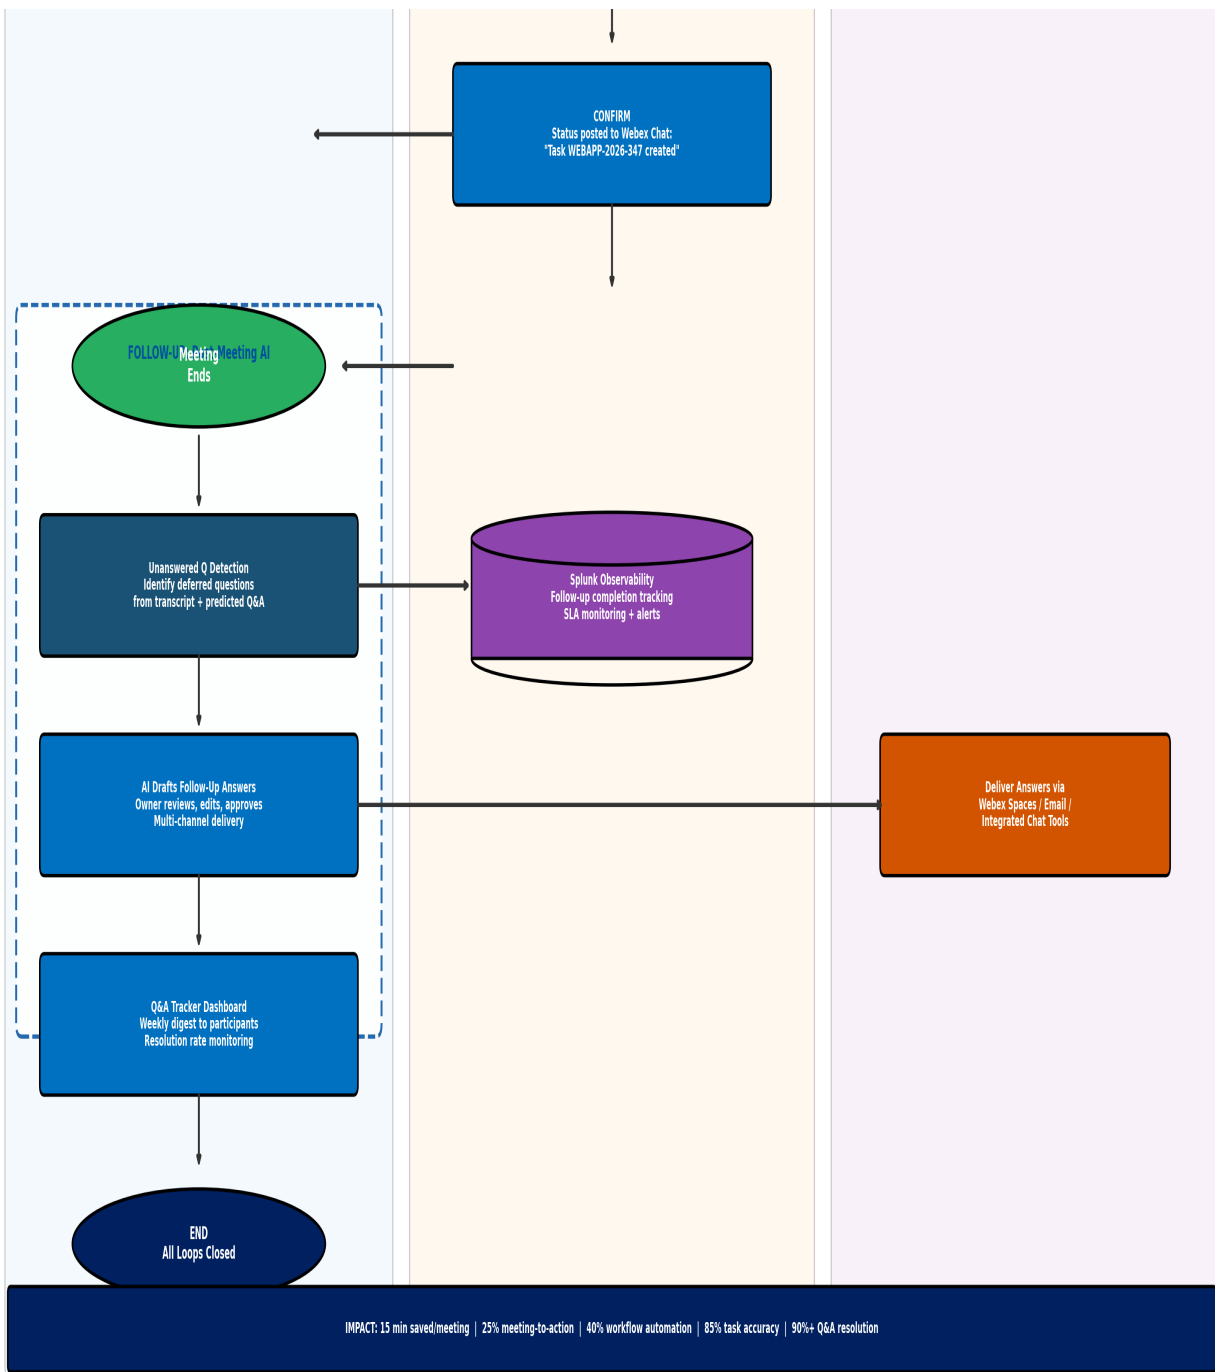

Solution 2 Flowchart: VIBE - Voice & Language Intelligence Layer

The following flowchart details the complete VIBE architecture including user onboarding, the live audio speak path, type-to-speak path, cross-language Q&A close-loop, session logging, privacy guarantee, tech stack, KPIs, and component architecture overview.

Solution 1: Webex AI Meeting Prep & Workflow Orchestrator

Prepare → Perceive → Reason → Act → Follow-Up | Full Meeting Lifecycle AI

Problem 3: Webex Has a Weaker, Less Strategic Developer Ecosystem

Problem Definition

Integration ecosystems are the hidden engines of collaboration platforms. Microsoft Teams offers over 2,000 integrations through its App Marketplace; Zoom supports over 2,500 third-party integrations. These platforms have become "glue layers" that connect nearly every SaaS tool an enterprise uses. Webex, while improving its integration catalog, still lags in scale, depth, and strategic positioning.

Beyond raw connector count, there is a second, more critical gap: intelligence. Today's integrations are mostly static, one-off connectors that perform simple, predefined actions. The next competitive frontier is AI-driven agents: intelligent, multi-step integrations that can observe, reason, and act autonomously inside a meeting. Yet no platform has launched a dedicated, enterprise-grade AI agent marketplace.

For Webex, this uneven ecosystem creates several problems:

- Reduced daily utility: Many users treat Webex as a "meetings-only" layer, reducing stickiness.
- Developer disinterest: Without a compelling differentiator, Webex struggles to attract high-quality AI builders.
- Procurement friction: A smaller ecosystem makes Webex an easier "tie-breaking loss" in enterprise evaluations.
- Limited new revenue streams: Webex relies on per-seat licensing with no material marketplace-style revenue.

Competitive I

- Microsoft Teams: Large app catalog on Microsoft 365 stack. Copilot operates inside Office apps but no formal AI agent marketplace with third-party AI agents.
- Zoom: Strong app marketplace with deep coverage. AI Companion provides early agentic behaviors but no fully open, certified AI agent ecosystem.
- Webex: Growing but smaller integration footprint, strong security capabilities, but no dedicated AI agent platform.

Business Imp

- Reduced daily utility and engagement
- Developer investment flows to Teams and Zoom
- Enterprise adoption friction in procurement decisions
- Revenue limitation without marketplace monetization

Solution 3: Webex Secure AI Agent Marketplace

Cisco will launch the Webex Secure AI Agent Marketplace, the industry's first enterprise-grade AI agent marketplace where any third-party developer can host AI agents inside Webex under strict Cisco-defined security, data, and UX rules. Like Apple and Google enforce standards for iOS/Android apps, Cisco enforces standards for AI agents in Webex. Developers build, Cisco certifies, admins control, users benefit. The marketplace operates on a four-stage lifecycle: Build, Certify, Deploy, Monitor.

Stage 1: BUILD - AI Agent SDK & Developer Environment

- Agent SDK (Python / JavaScript): Pre-built components for common patterns: Meeting Listener, Task Executor, Data Retriever, Notification Sender.
- Agent Templates: CRM Updater, Ticket Creator, Doc Generator, Calendar Scheduler, Contract Flow (DocuSign), VIBE Voice Agent (first-party). Templates reduce

development time by 60%.

- Sandbox Environment: Simulated meetings, API calls, and data flows. Tests: latency, accuracy, error handling, load performance.
- API & A2A Reference: Meeting lifecycle, real-time transcription feeds, user-context APIs, Agent-to-Agent protocols for cross-tool orchestration with Jira, Salesforce, Slack, SAP, DocuSign, ServiceNow, GitHub.

Stage 2: CERTIFY - Cisco Security & Compliance Pipeline

- Static Code Analysis: Scanning for vulnerabilities, backdoors, data-exfiltration patterns, insecure API usage.
- Permission & Scope Validation: Declared vs actual data access verification. Zero-trust minimum-privilege enforcement.
- Performance & Reliability Testing: Latency benchmarks (<200ms), load testing (1,000+ concurrent users), CPU/memory profiling, failure-recovery validation.
- Compliance Checks: SOC 2, HIPAA, FedRAMP, GDPR automated checks based on declared data-handling practices.
- Cisco Trust Badge: "Cisco Verified Agent" badge signals enterprise-grade security and compliance standards.

Stage 3: DEPLOY - Enterprise-Grade Management & Deployment

- Marketplace Discovery: Admins browse by industry vertical (healthcare, finance, government, manufacturing), use case (sales, support, HR, engineering), and security/compliance level.
- Configuration & Scoping: Assign to orgs/teams/users. Data access levels: read-only, limited write, full write. Approval workflows for high-risk actions. Usage quotas and budget caps.
- Sandboxed Execution: Isolated containers in Webex Cloud with zero-trust identity layer, network egress filtering, and rate limits.
- Pilot Rollout & A/B Testing: Deploy to pilot groups first, measure time saved, ticket rate, user satisfaction before organization-wide activation.

Stage 4: MONITOR - Splunk-Powered Observability & Governance

- Real-Time Dashboards: Per-agent metrics (invocations/hour, success/error rate, API latency). Aggregated usage by org/team/user. Active agent count.
- Anomaly Detection: ML-based detection of unusual data-access patterns, permission violations, performance regressions, unauthorized API attempts, cross-tenant data flags.
- Kill-Switch & Audit Trail: Instant agent deactivation with full audit trail retained. Scope and quota adjustment.
- Billing & Revenue: Usage tracked per agent. Pay-per-use or subscription models. 70/30 revenue split (developer-favoring). Monthly invoice generation.

User Journey Within Webex

The marketplace integrates seamlessly into the Webex user experience:

- Users discover agents through the "AI Agents" tab in Webex or via in-meeting suggestion banners.
- Users review agent permissions (e.g., "Can read transcript, can create Jira tickets") and accept Cisco's data notice before installation.
- During live meetings, agents detect task intents from the transcript, pull context from connected systems, and draft complete actions inline in Webex.
- Users see in-meeting approval cards with Approve, Edit, or Reject controls before any action is executed.

- On approval, agents execute via authenticated API calls. Webex confirms in chat (e.g., "Jira ticket WEBAPP-2026-347 created. Assigned to Sarah Chen. Priority: High.").
- Users manage agents through a "My Agents" panel: disable, update, downgrade, or view usage history.

Why This Solution Wins

- Trust-First AI: Cisco's security certifications and Splunk observability create governance that neither Microsoft nor Zoom can match for regulated industries.
- Platform-Level Differentiation: Webex competes on "who has the most intelligent, safest AI agent ecosystem" rather than "who has more connectors."
- New Revenue & Network Effects: Per-seat plus per-agent monetization creates a self-reinforcing flywheel: more agents lead to more value, more users, more developers.

Expected Imp

- 500+ certified AI agents in the marketplace within Year 1
- \$150 million in GMV by FY2028
- 3x growth in Webex developer activity within 18 months
- 85% enterprise renewal rate driven by agent-based stickiness
- New annual marketplace commission revenue: \$50 million by FY2029

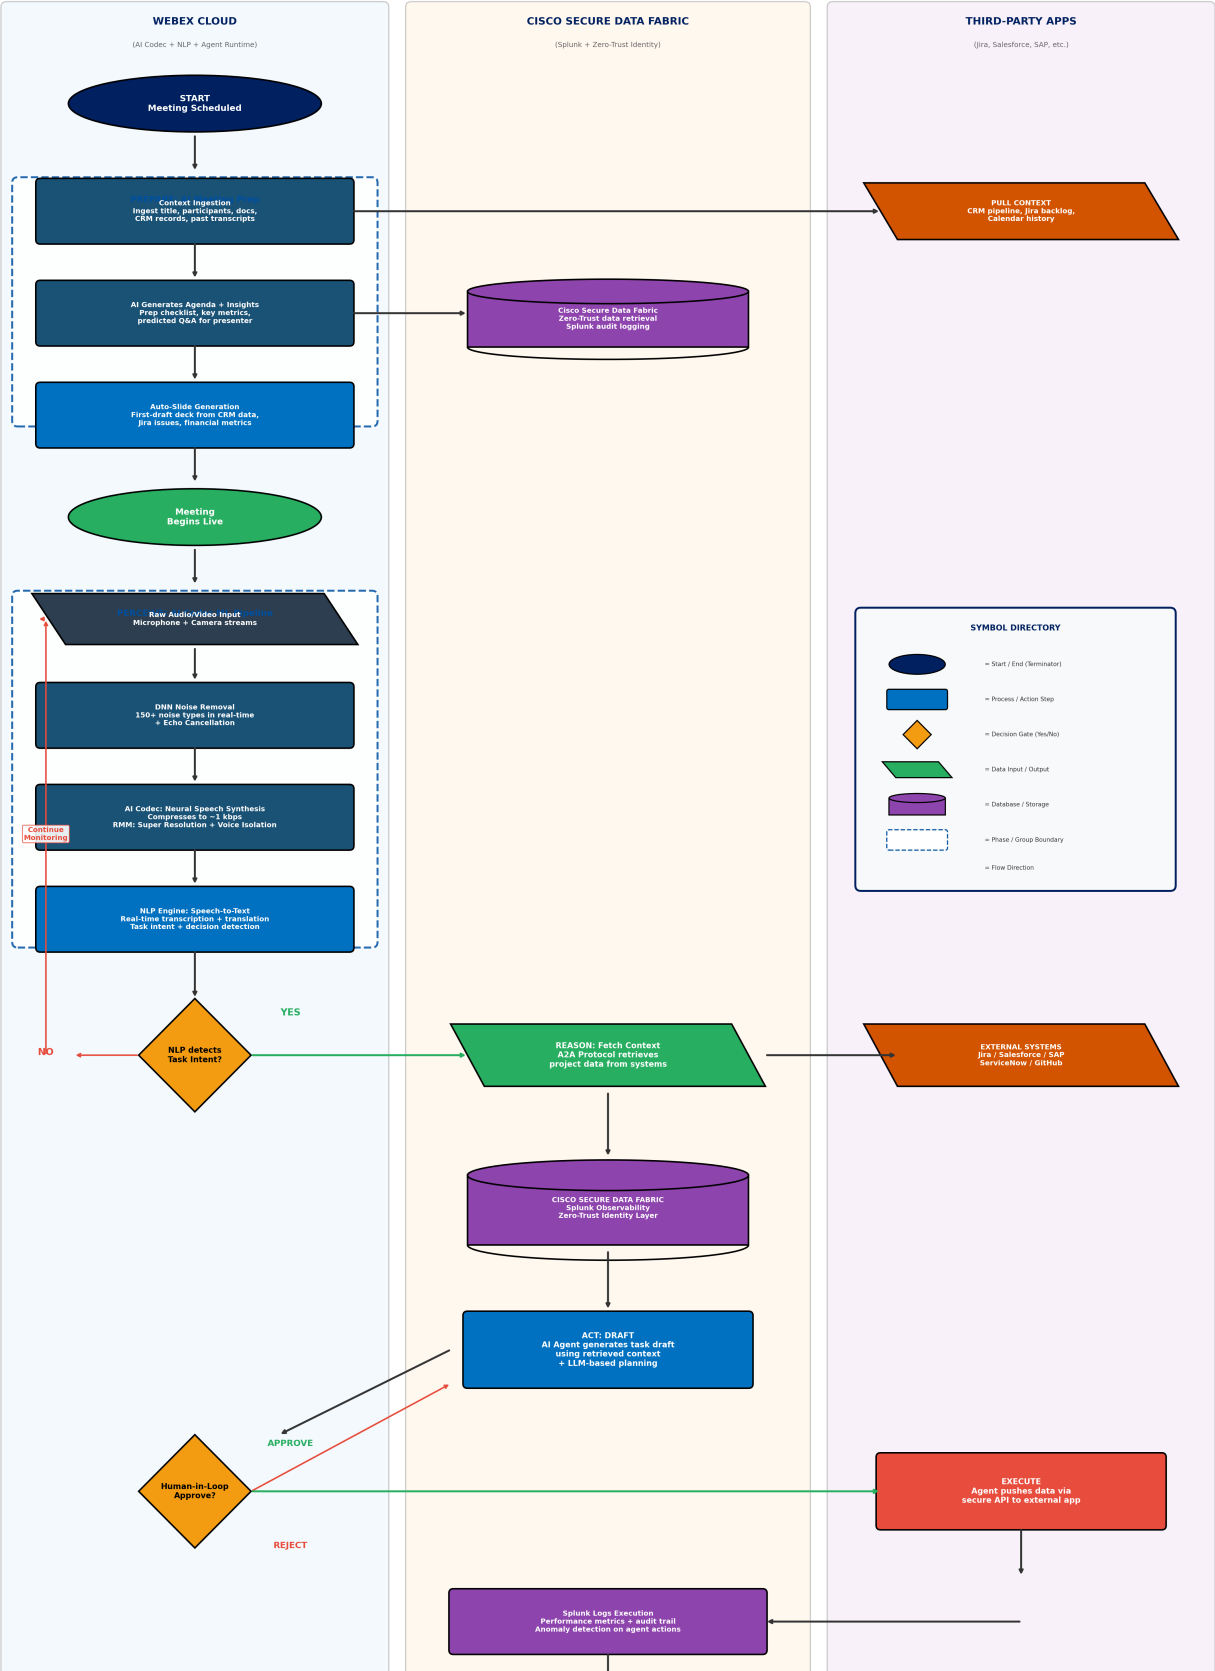

Sources: Cisco FY2024 10-K; Splunk platform documentation; Salesforce AppExchange economics model; MarketsandMarkets Agentic AI Market Report 2024.

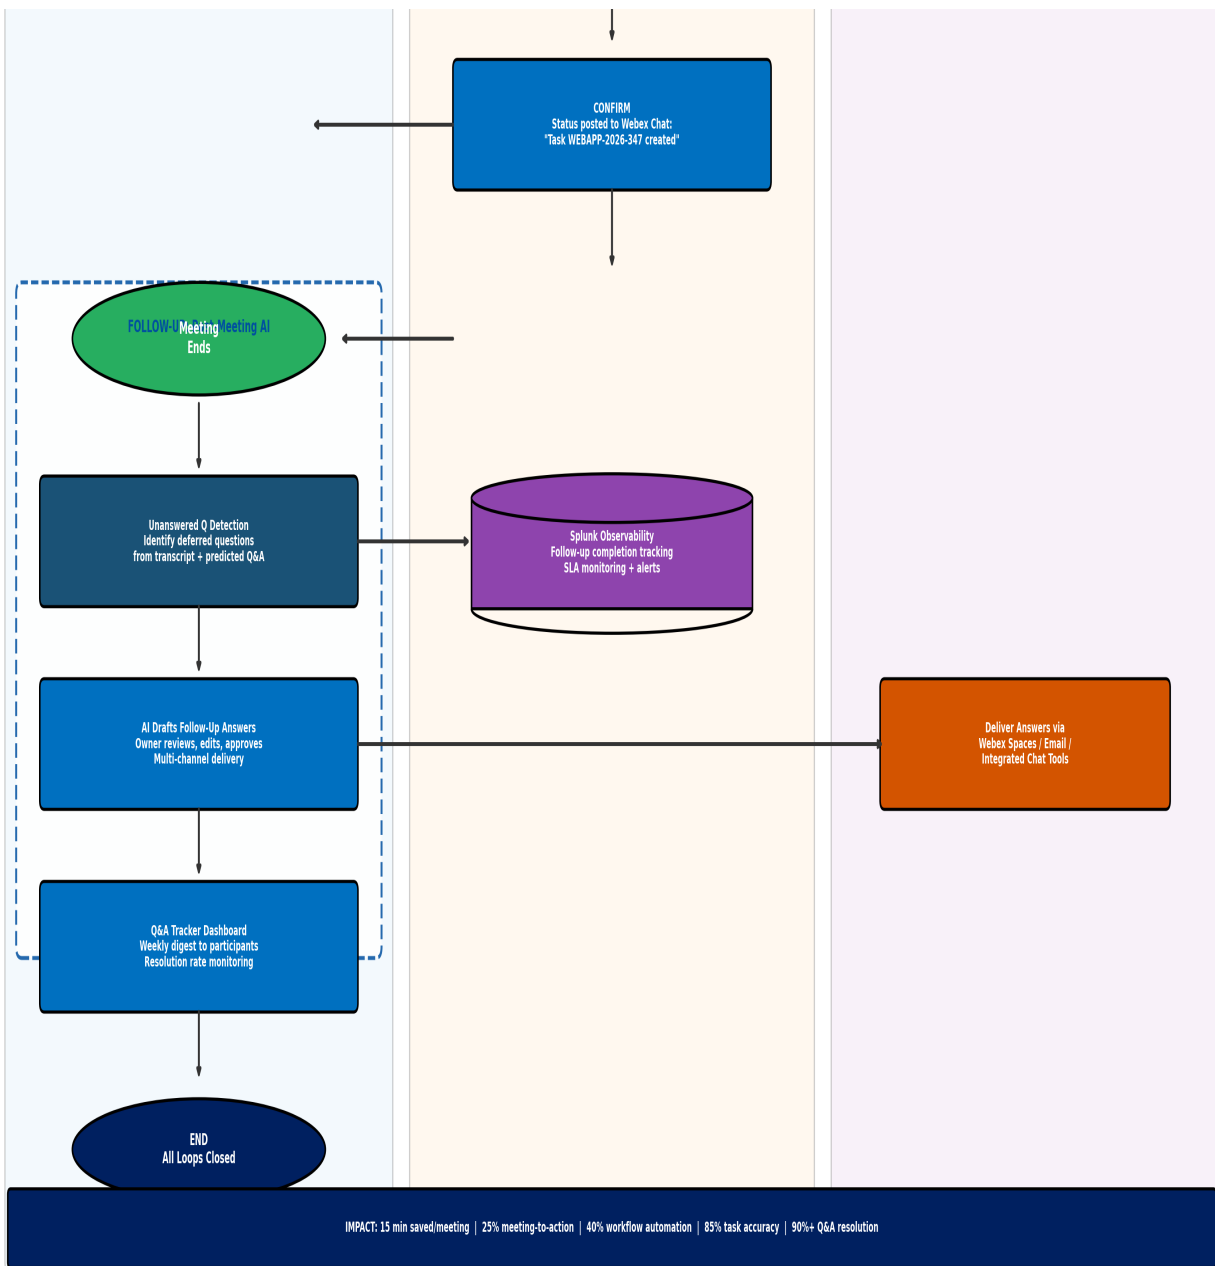

Solution 3 Flowchart: Secure AI Agent Marketplace

The following flowchart details the three-lane architecture (Developer Journey, Admin Journey, User Journey), the Cisco certification pipeline, Splunk observability layer, agent examples, industry coverage, and platform architecture stack.

Solution 1: Webex AI Meeting Prep & Workflow Orchestrator

Prepare → Perceive → Reason → Act → Follow-Up | Full Meeting Lifecycle AI

Technical Feasibility, Constraints & Scalability Assessment

This section assesses the technical feasibility, key constraints, and scalability considerations for each of the three proposed solutions.

Solution 1: AI Meeting Prep & Workflow Orchestrator

Technical Feasibility

- The Webex AI Codec already exists in production and processes millions of meeting minutes daily. Extending the NLP layer to detect task intents is an incremental ML advancement.
- LLM-based task planning is technically proven. Fine-tuning a model on enterprise meeting transcripts achieves high accuracy for task detection and drafting.
- A2A protocols for cross-system integration rely on mature REST/GraphQL APIs.
- The PREPARE phase leverages retrieval-augmented generation (RAG), a well-established pattern.

Key Constraints

- Latency: Real-time task detection requires the NLP pipeline to process audio-to-intent in under 2 seconds.
- LLM hallucination risk: Mitigated by human-in-the-loop approval and confidence thresholds.
- Enterprise data access: Organizations with strict governance may limit what Webex AI can ingest.

Scalability

- Cisco's cloud infrastructure supports 600+ million meeting minutes per month.
- The A2A protocol is stateless and horizontally scalable.
- Splunk observability handles petabytes per day.

Solution 2: VIBE - Voice & Language Intelligence Layer

Technical Feasibility

- DNN noise removal and voice processing are already core Webex AI Codec capabilities.
- ASR at 98% accuracy is achievable using Whisper or Cisco's proprietary ASR. 100+ language support via neural machine translation models deployed at scale.
- Neural TTS with natural voice personas is technically mature (Google Cloud TTS, Amazon Polly, open-source models).
- Simple Mode jargon simplification is a well-understood NLP task with strong performance from current models.

Key Constraints

- End-to-end latency: The full pipeline (ASR + translation + simplification + TTS) must complete in under 2 seconds. Pipeline parallelization and model optimization are required.
- Translation accuracy for domain-specific terms: Custom terminology dictionaries per organization needed.
- Bandwidth: Per-user VIBE audio streams increase requirements. Mitigated by neural codec compression (1 kbps).

Scalability

- VIBE processing is per-user and per-meeting, naturally parallelizable.
- Neural machine translation models deploy as auto-scaling microservices.
- Splunk ingests VIBE telemetry (voice quality, translation accuracy, TTS events) across

- all meetings for centralized analytics and anomaly detection at enterprise scale.
- Zero data retention option simplifies storage scalability.

Solution 3: Secure AI Agent Marketplace

Technical Feasibility

- SDK development is standard engineering. Extending existing Webex APIs into a structured agent SDK is feasible within 6-9 months.
- The certification pipeline leverages existing Cisco capabilities: static analysis, zero-trust networking, and Splunk observability.
- Sandboxed agent execution using containerized environments is a proven pattern (AWS Lambda, Cloudflare Workers).

Key Constraints

- Certification throughput: Automated scanning handles volume; manual review of edge cases may create bottlenecks.
- Agent quality control: The certification bar must balance trust with developer accessibility.
- Cross-system compatibility: Agents depend on third-party APIs remaining stable.

Scalability

- Agent execution scales horizontally via isolated containers with defined resource limits.
- Splunk monitoring handles millions of agent events per day.
- The marketplace catalog scales trivially as a CDN-backed web application.

Implementation Risks & System-Level Trade-Offs

This section identifies key implementation risks and system-level trade-offs for each solution.

Solution 1: AI Meeting Prep & Workflow Orchestrator

Implementation Risks

- AI hallucination in task drafts: Mitigated by mandatory human-in-the-loop approval and confidence scoring.
- Over-automation backlash: Mitigated by progressive disclosure and user-controlled sensitivity settings.
- Data privacy and compliance: All data access passes through zero-trust data fabric with explicit consent.
- Integration fragility: Mitigated by circuit-breaker patterns and graceful degradation.

System-Level Trade-Offs

- Accuracy vs. speed: More context retrieval improves quality but increases latency.
- Automation vs. control: Human-in-the-loop reduces speed but is essential for trust in regulated industries.
- Breadth vs. depth of integration: Prioritize top 10-15 enterprise tools for deep integration; use generic connectors for long-tail.

Solution 2: VIBE

Implementation Risks

- Deepfake perception risk: Mitigated by mandatory on-screen labeling, meeting-start notification, and admin controls.
- Translation errors in high-stakes contexts: Mitigated by custom terminology dictionaries and confidence scoring with visual warnings.
- User adoption resistance: VIBE is fully opt-in with per-user control; no organizational mandate required.
- Compute cost: VIBE processing activates only for users who enable it; adaptive quality scaling for large meetings.

System-Level Trade-Offs

- Latency vs. quality: Larger models improve accuracy but increase inference time.
- Privacy vs. personalization: Zero-data-retention limits personalization for privacy-conscious users.
- Simplification vs. accuracy: Over-simplification may distort meaning. Original text always provided alongside simplified version.

Solution 3: AI Agent Marketplace

Implementation Risks

- Marketplace cold-start problem: Mitigated by seeding 20-30 first-party agents, ISV partnerships, and developer grants.
- Security certification bottleneck: Automated scanning handles 90%+; manual review reserved for sensitive-data agents.
- Agent misbehavior in production: Mitigated by kill-switch, sandboxed execution, and Splunk anomaly detection.
- Revenue model uncertainty: Start with generous developer split; adjust as marketplace matures.

System-Level Trade-Offs

- Openness vs. security: Trust-first approach grows slower but builds stronger enterprise trust. Correct for Cisco's brand.
- First-party vs. third-party agents: Recommended 15-20% first-party for core use cases; 80%+ from developer community.
- Platform lock-in vs. portability: Adopt open standards (A2A protocol) to reduce perceived lock-in while maintaining differentiation.

Integrated Strategy: How the Three Solutions Work Together

The three solutions are designed as an integrated system, not independent initiatives:

- Solution 1 (AI Meeting Prep & Workflow Orchestrator) provides the core intelligence: AI that can prepare, perceive, reason, act, and follow up across the full meeting lifecycle.
- Solution 2 (VIBE) ensures every participant can fully engage regardless of language, technical background, or environment. VIBE makes the input to Solution 1 richer and more inclusive.
- Solution 3 (AI Agent Marketplace) scales the intelligence: the marketplace enables hundreds of developers to build vertical-specific agents and provides the deployment and governance infrastructure for regulated industries.

The combined impact makes Webex indispensable rather than interchangeable. Users stay on Webex not because the video quality is marginally better, but because leaving means losing their AI agents, their automated workflows, the productivity gains that accumulate over time, and the inclusive communication layer that makes global teamwork seamless.

Combined Projected Impact

Metric	Projected Value
Daily Active Usage Increase	+35% within 12 months of full deployment
Meeting-to-Action Conversion	25% (vs. current ~5% industry average)
Post-Meeting Follow-Up Time	Reduced from 45 min to 5 min per meeting
Action Item Completion Rate	92% on-time (vs. 27% industry baseline)
Non-Native Speaker Participation	+40% increase in active contribution
Translation Latency	<1 second end-to-end for 100+ languages
Marketplace Certified Agents	500+ in Year 1, 2,000+ by Year 3
Developer Ecosystem Growth	3x within 18 months
Enterprise Renewal Rate	85% (driven by agent + VIBE stickiness)
Incremental Collaboration ARR	+\$2.1 billion by FY2029
Marketplace Commission Revenue	\$50M annually by FY2029
Productivity Savings per Worker	\$4,200 per knowledge worker per year
